## 1 Preprocessing

Given a directed acyclic graph  $G = (V, E)$  and two vertices  $s$  and  $t$ ,  $|V|=n$  and  $|E|=m$ .

Initialize a boolean array `isCutVertex` of size  $n$  with all values set to false. This array contains the result of the algorithm where the vertices marked as true are the output or the  $s$ - $t$  cut vertices.

We will follow 1-based indexing.

## 2 Algorithm Description

1. Perform Topological Sort using DFS (as done in lectures).

If after sort  $t$  does not appear after  $s$ , this means that there is no path from  $s$  to  $t$ , simply return.

Else copy the sorted vertices to an array named `TopoArr` such that first vertex is  $s$  and last vertex is  $t$ , i.e. copy a subarray from  $s$  to  $t$  from the original sorted result so that first vertex is  $s$  and last vertex is  $t$ .

`TopoArr` contains a path from  $s$  to  $t$ , so if there exists any cut vertex it should be one of these vertices except  $s$  and  $t$ . This statement holds true due to the graph being directed and acyclic.

2. Now we need to check whether every vertex in `TopoArr` is a cut vertex.

A vertex  $v$  in `TopoArr` is a cut vertex iff there doesn't exist an edge  $u \rightarrow w$ , where  $u$  occurs before  $v$  and  $w$  occurs after  $v$  in `TopoArr`. This means that removing  $v$  will disconnect the path between  $s$  and  $t$  as there will be no other way to connect vertices before and after  $v$ .

Initialize two integer arrays `InDegree` and `OutDegree` of size of `TopoArr`, with all values set as number of inward edges from vertices in `TopoArr` to a given vertex in `InDegree` and number of outward edges to vertices in `TopoArr` from a given vertex in `OutDegree`. For this, take a vertex from `TopoArr` and check remaining vertices in `TopoArr` for inward and outward edge from adjacency matrix and set values accordingly.

3. To check the above condition, we initialize a counter with out-degree of  $s$ .

Then we iterate over sorted vertices in `TopoArr` except( $s$  and  $t$ ), i.e. 2 to  $|\text{TopoArr}|-1$  where  $|\text{TopoArr}|$  means size of `TopoArr`.

In each iteration for vertex  $v$ , decreament the counter by `InDegree[v]`. If counter equals 0, this means  $v$  is a cut vertex, set `isCutVertex[v]` to true. Then increament the counter by `OutDegree[v]` and proceed to next iteration.

## 3 Proof of Correctness

The proof of correctness involves proving that all  $s$ - $t$  cut vertices are present in `TopoArr` (step 1 according to description) and the `FindCutVertex` function (step 3 according to description) works correctly.

The topological sort on a directed acyclic graph returns vertices in an order, where if there exists an edge  $u \rightarrow v$  then  $u$  will occur before (not necessary immediate before)  $v$  in the topological sort.

Let  $u$  be any vertex before  $s$  which has an edge to  $t$ , for  $u$  to be a cut vertex there should exist an edge  $s \rightarrow u$  which will then form a path outside vertices of `TopoArr`, but this cannot happen since  $u$  occurs before  $s$  there is no edge  $s \rightarrow u$ , otherwise it contradicts property of topological sort.

Let  $u$  be any vertex after  $t$  which has an edge from  $s$ , for  $u$  to be a cut vertex there should exist an edge  $u \rightarrow t$  which will then form a path outside vertices of `TopoArr`, but this cannot happen since  $u$  occurs before  $t$  there is no edge  $u \rightarrow t$ , otherwise it contradicts property of topological sort.

In any iteration in `FindCutVertex` for vertex  $v$ , if counter equals 0 this means that the remaining outward edges of vertices before  $v$  (which were not balanced by an inward edge) are balanced by inward edges of  $v$ , signifying all vertices

before  $v$  have no edge with a vertex after  $v$  in the TopoArr. This implies that all of the possible paths from  $s$  to  $t$  must pass through  $v$  and hence  $v$  is a  $s$ - $t$  cut vertex.

## 4 Pseudocode

---

```
1: function FINDCUTVERTEX(TopoArr, InDegree, OutDegree, s, t, isCutVertex)
2:   counter = OutDegree[s]
3:   for (i : 2 to |TopoArr|-1):
4:     v = TopoArr[i]
5:     counter = counter - InDegree[v]
6:     if(counter == 0):
7:       isCutVertex[v] = true
8:       print(v)
9:     counter = counter + OutDegree[v]
10: end function
```

---

## 5 Complexity Analysis

### 5.1 Time complexity

Initializing isCutVertex are linear time operations, i.e.  $O(n)$ . Topological sort using DFS takes  $O(n+m)$  time as each vertex and edge is checked once. Copying a subarray of above result takes  $O(n)$  time in worst case. Initializing InDegree and OutDegree is also  $O(n^2)$  in worst case. Checking whether every vertex is a cut-vertex involves iterating TopoArr once resulting in  $O(n)$  time operation.

So the overall run time complexity of the algorithm is  $O(\max(n^2, n+m))$ .

### 5.2 Space complexity

The algorithm uses two additional arrays of size  $n$  to solve the problem and one array to return the result. So the overall space complexity of the algorithm is  $O(n)$ .
